

# **Vision of Internet platform and QoS Framework**

# Objective

- To study performance and QoS of the platform
  - Response time
  - throughput
  - end-to-end delay

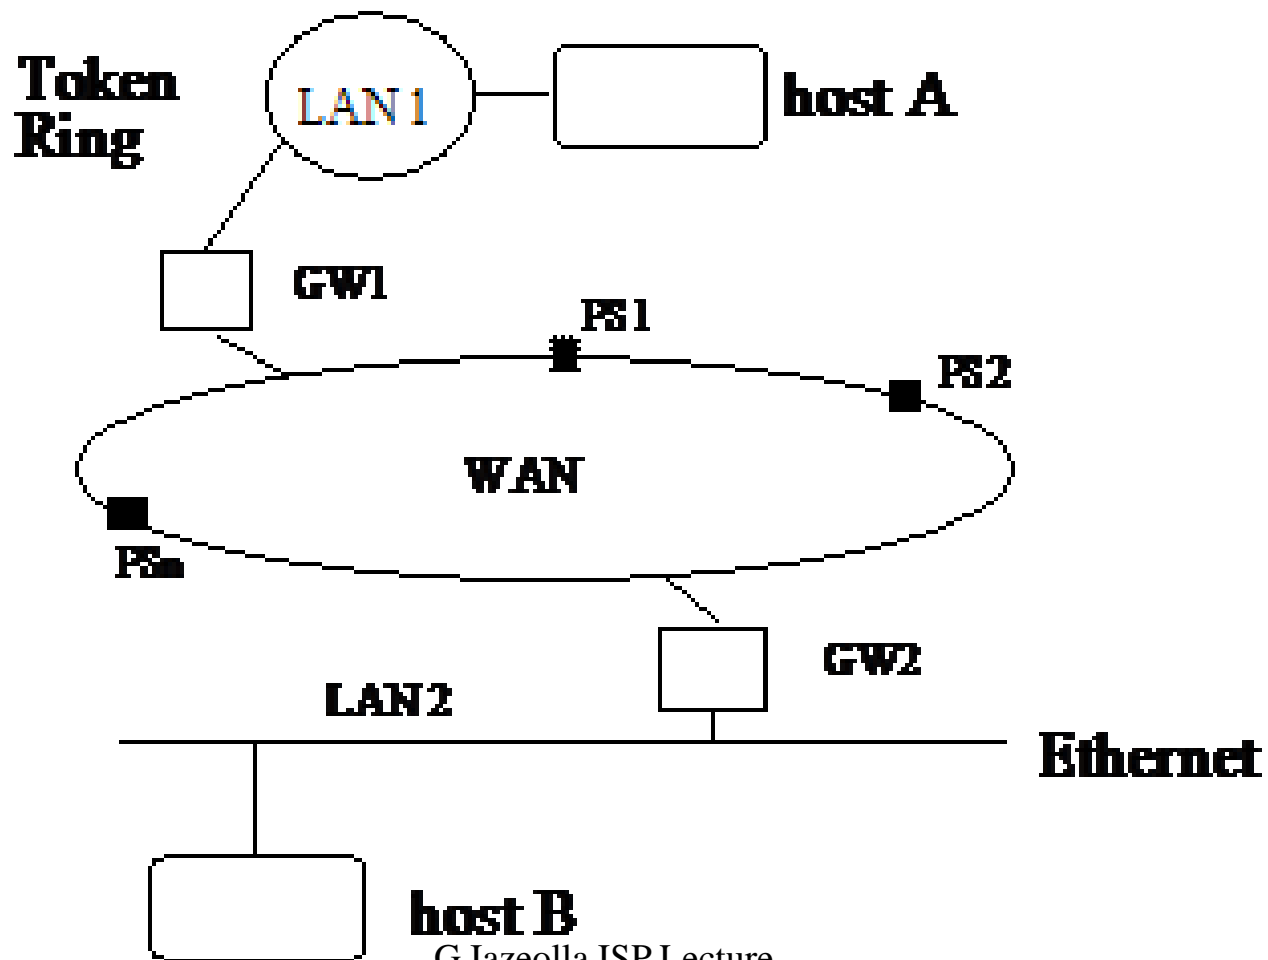

# Multihost vision: internet platform

(PS= packet switch node in WAN)

# Single-host vision: internet platform

(PS= packet switch nodes in WAN)

# Single host vision and internet user platform

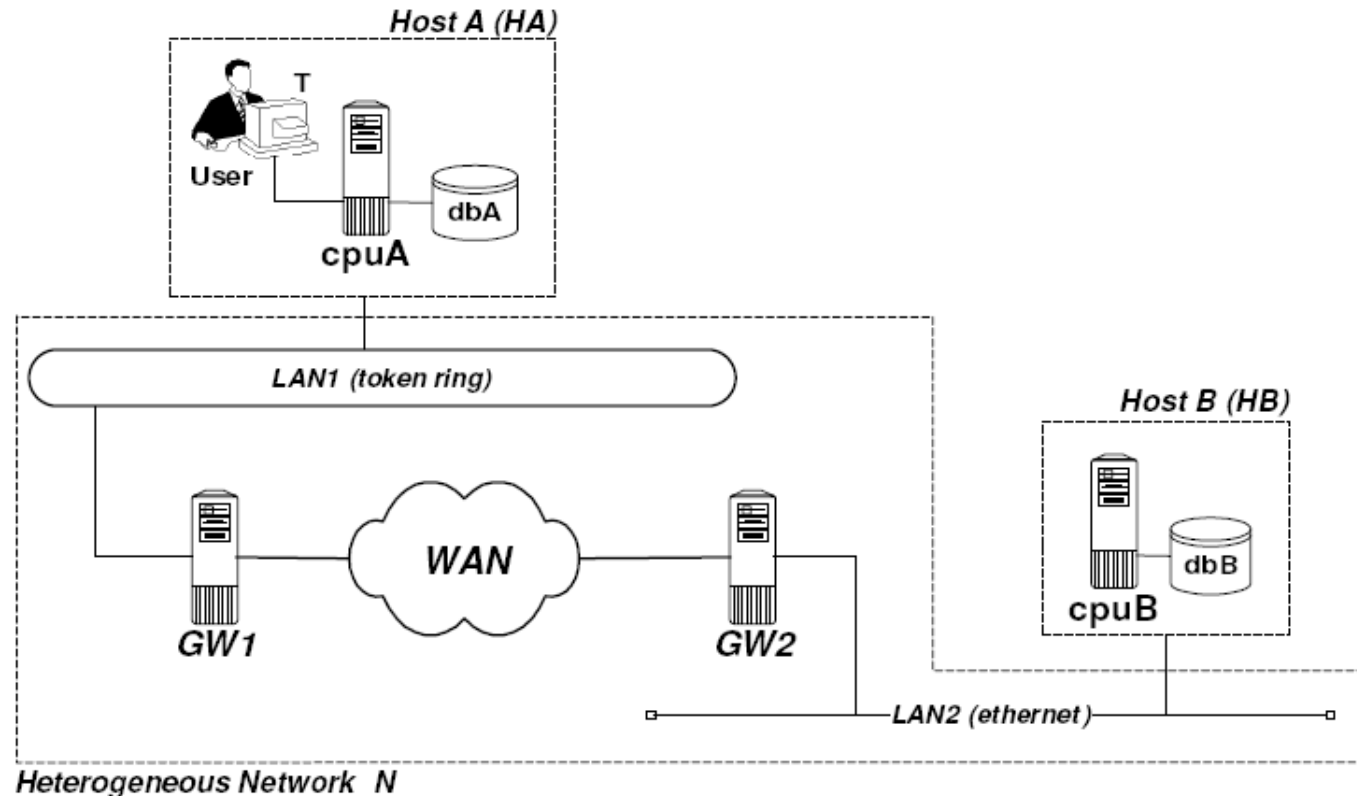

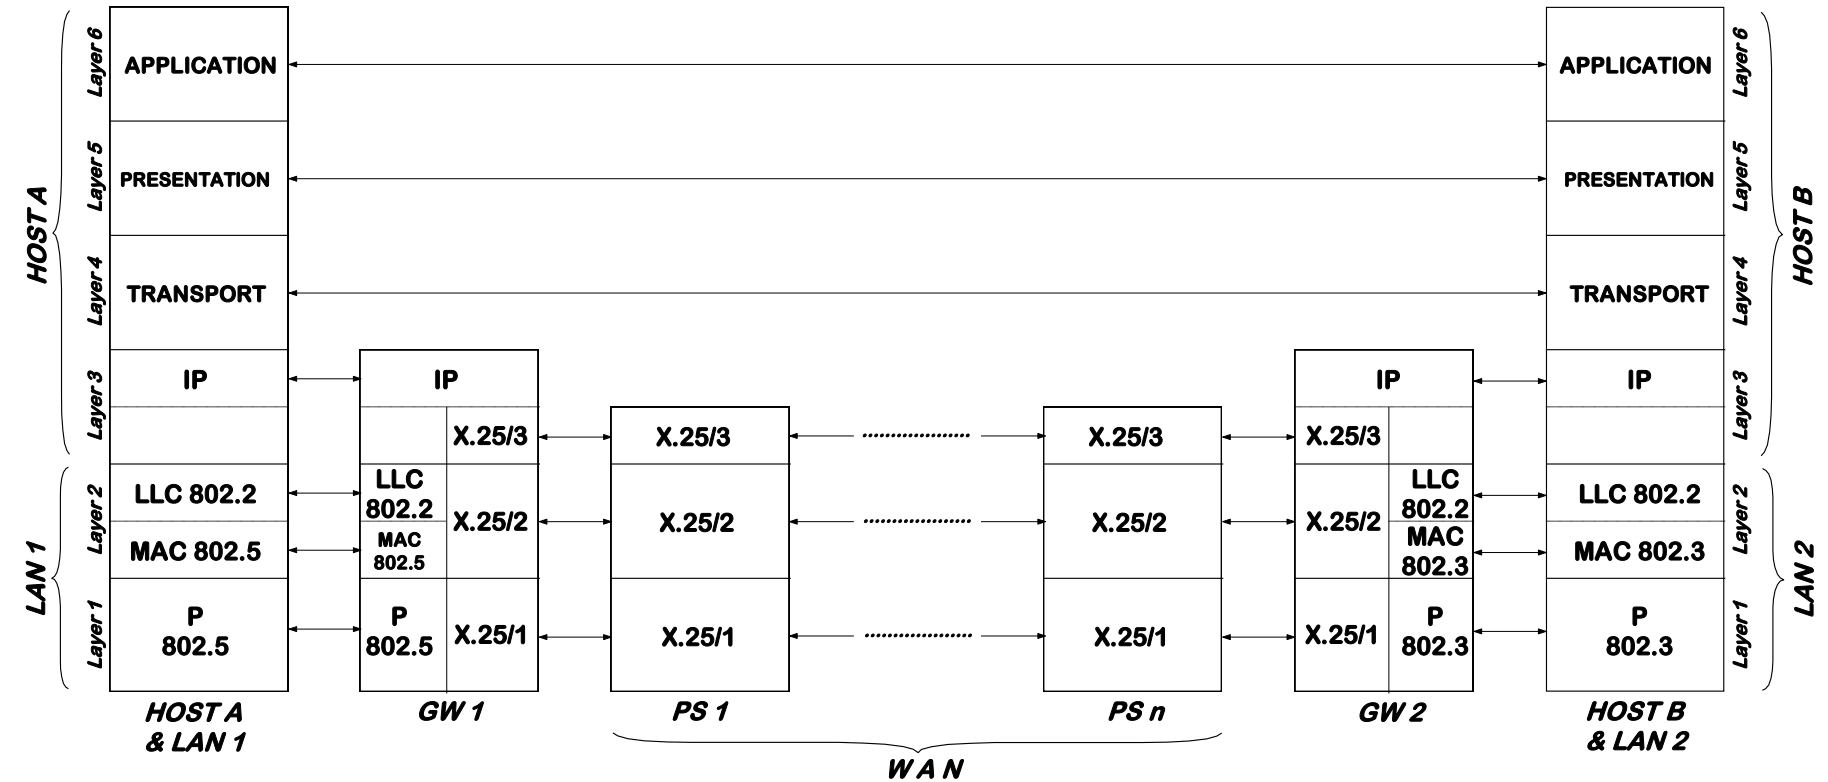

Fig. 1. General view of the system platform

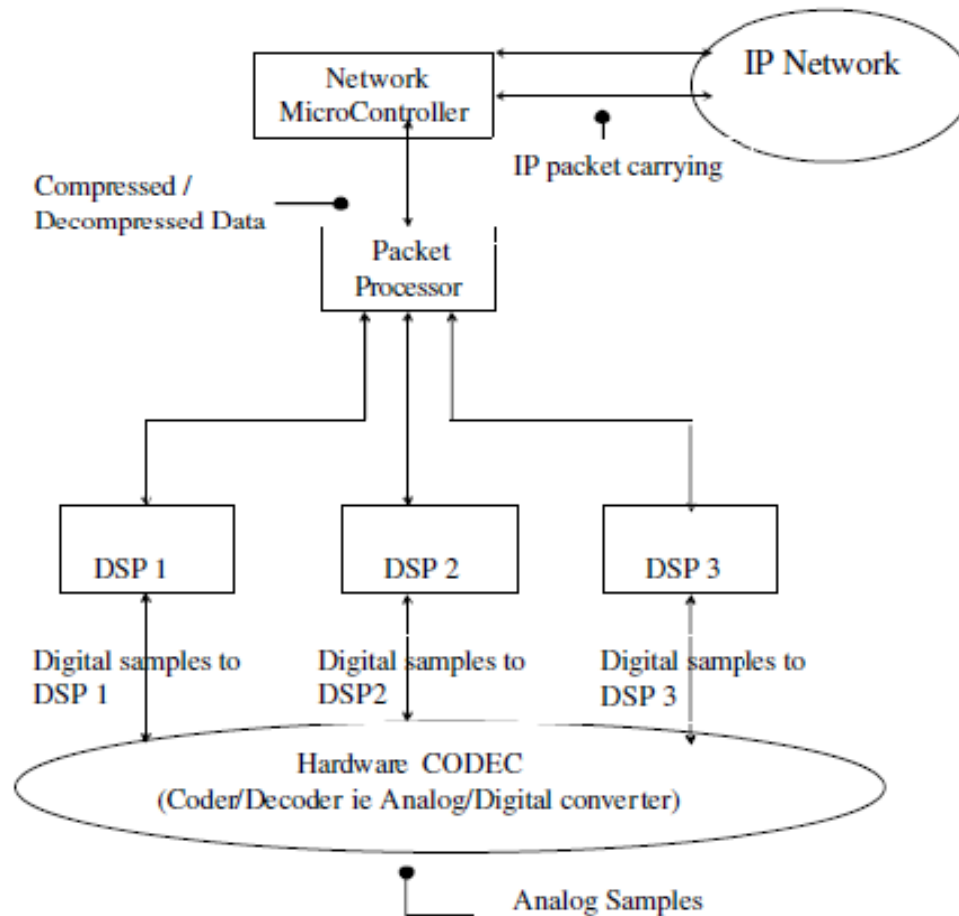

# Protocol recall

## Description of protocols

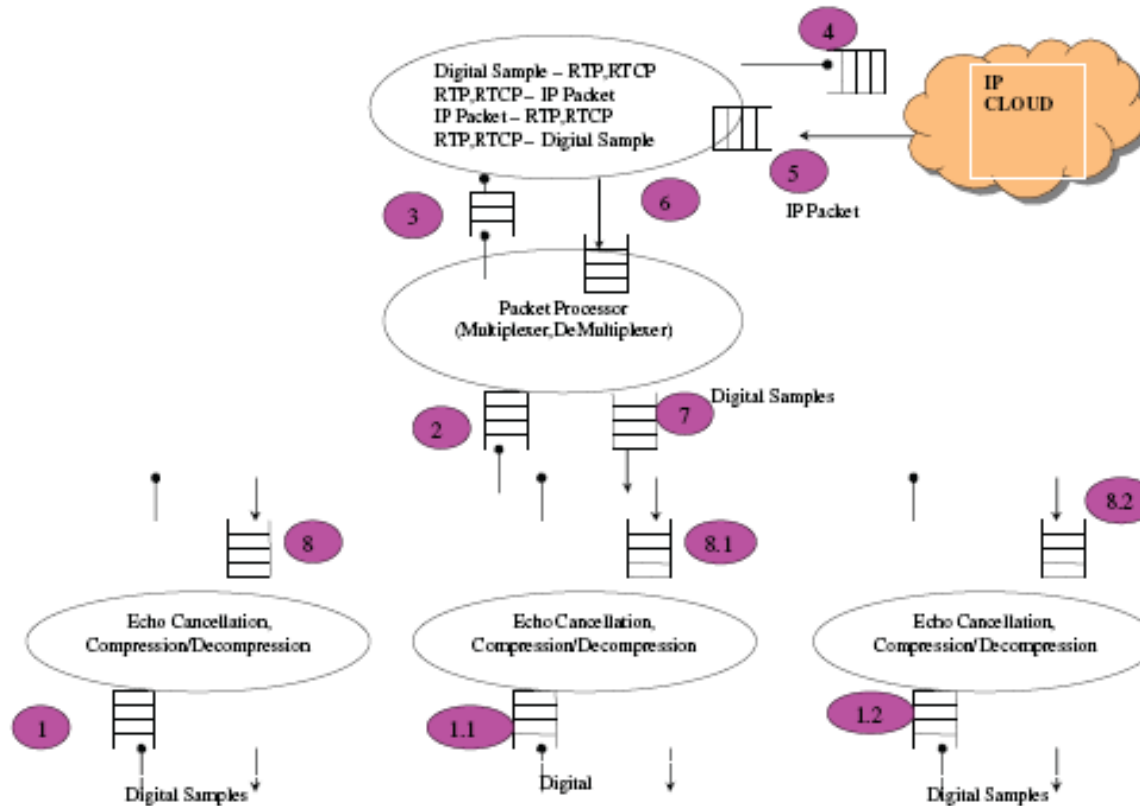

- Layer 6: Application layer
- Layer 5: Presentation layer
- Layer 4: Transport layer (protoc. **TCP**)
- Layer 3: Network layer (protoc. **IP**)
- Layer 2: Distinto in
  - Logical **L**ink **C**ontrol sub-layer (protoc. **LLC**) e
  - Media **A**ccess **C**ontrol sub-layer (protoc. **MAC**)
- Layer 1: Physical layer (protoc. **P**)

# Architecture of a VoIP Gateway

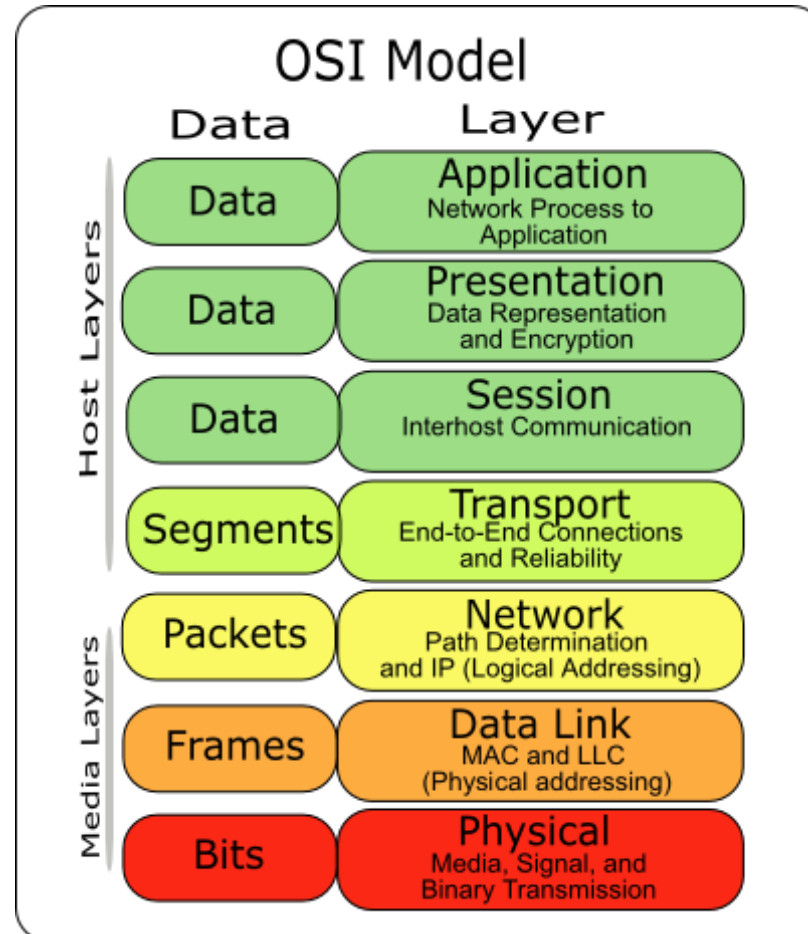

# Performance model of a VoIP Gateway

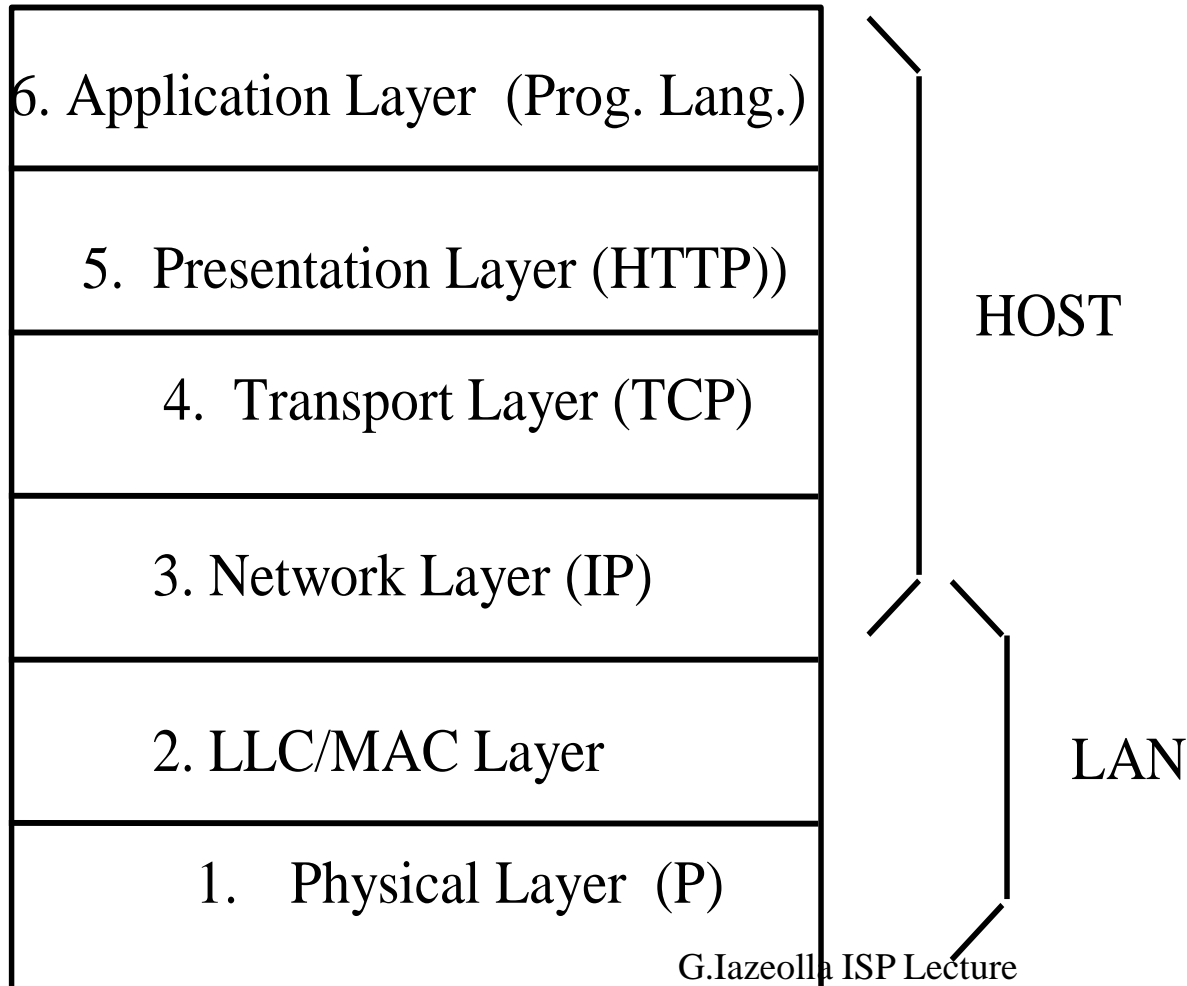

The OSI (Open System Interconnection) reference model (also known as the ISO/OSI model)

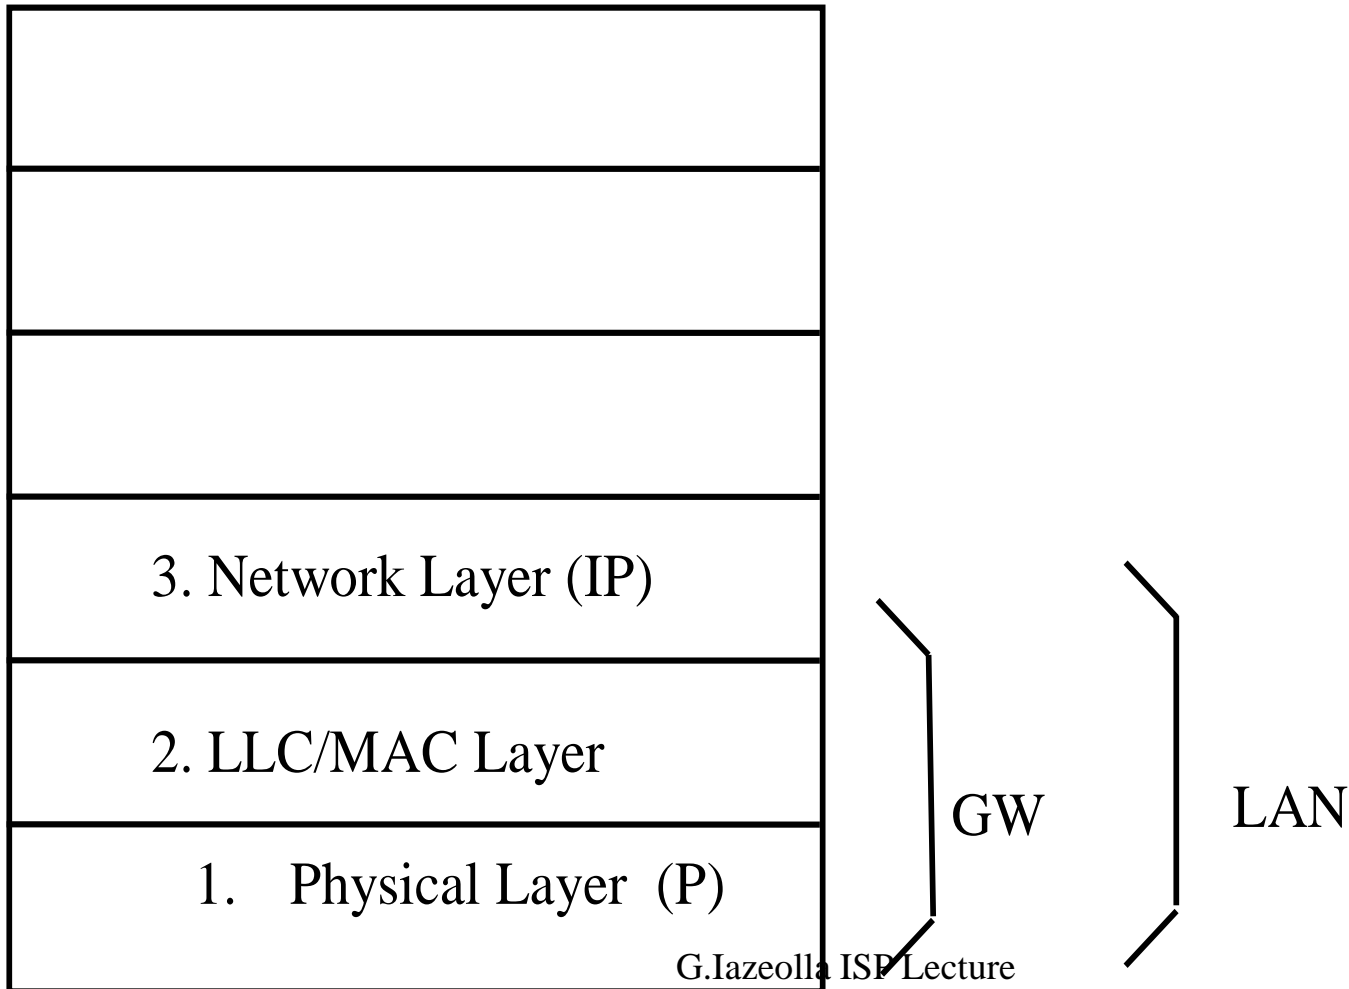

Vision of the Host Layers and the Media Layers

***vertical description of the network  
functions  
(from HOST towards LAN)***

*vertical description of the network  
functions  
(from LAN towards Gateway)*

*Vertical description of the network functions*  
**Through virtual machines (or *abstract*)**

*Functionality of the network described by the various **abstraction levels***

from the bottom to the top: progressive **virtualization** of the network

**VM<sub>1</sub>** hardware or physical machine (**circuit** level) *protoc. P*

**VM<sub>2</sub>** firmware machine (**microprogram** language network level) *protoc. MAC/LLC*

**VM<sub>3</sub>** network layer machine (**network** language level) *protoc. IP*

**VM<sub>4</sub>** transport layer machine (network **operating system** language level) *protoc. TCP*

**VM<sub>5</sub>** presentation layer machine (*presentation towards network language level*) *prot. HTTP or others*

**VM<sub>6</sub>** user program level (**user** programming language level)

# Network/Transport/ Presentation level protocols

- *Network/Transport* Internet level protocol :  
TCP/IP (Transmission Control Protocol/Internet Protocol).
- *Transport/Presentation* level protocols.
  - Hypertext Transfer Protocol (HTTP) – for the transmission of information via the WEB
  - Simple Mail Transfer Protocol (SMTP) – for the management of electronic mail messages
  - Network News Transfer Protocol (NNTP) – for the management of discussion groups
  - File Transfer Protocol (FTP) - for the transfer of files between remote machines

## *Vertical description of the network*

**platform (hardware-part) =**  
( VM<sub>1</sub>, VM<sub>2</sub> )

**platform (system-part (software)) =**  
(VM<sub>3</sub> , VM<sub>4</sub>)

**User (software) workload=**  
(VM<sub>5</sub> , VM<sub>6</sub> )

## *Vertical description of the network functions*

Machine  $VM_i$

is

- set of resources  $R_i$
- Language for their use  $L_i$

## *Vertical description of the network functions*

Each primitive (instruction or command) of  
Language  $L_i$

is created by a program written in the  $L_{i-1}$

Language of  $VM_{i-1}$  machine

## *Vertical description*

- $VM_1$  physical layer (in LAN & GW)
  - resource  $R_1$  = physical components (electrical, electronic), connections among these etc.
  - language  $L_1$  = undefined
    - in that level 1 is the only one where the functionalities aren't further emulated

## *Vertical description*

- $VM_2$  LLC/MAC Layer (in LAN & GW) machine
  - $R_2$  resources = internal registers, logic-arithmetic operators, sequencer, controllers, shifters, transfer networks, etc.
  - $L_2$  language = microprogram language
    - uses resource  $R_2$
    - its (micro)instructions or (micro)commands are directly interpreted by the physical machine  $VM_1$

## *Vertical description*

- $VM_3$  IP Layer (in HOST)
- - resources  $R_3$  = memory locations (main, secondary), addressable registers of processors (main and peripheral or I/O), logic-arithmetic unit, control etc.
  - language  $L_3$  = **base language of** HOST  
(machine language) in binary
    - uses  $R_3$  resources
    - each instruction or command written in  $L_3$  is implemented by a microprogram written with (micro)instructions of language  $L_2$  of  $VM_2$

## *Vertical description*

- VM<sub>4</sub> Transport Layer (in HOST)
  - resources R<sub>4</sub> = physical *spaces* of memory (main and secondary), *physical* processors as a whole (main, peripheral) etc.,
  - L<sub>4</sub> language = **operating system language** of HOST for programming *assignment procedures* R<sub>4</sub> resources according to the need which begin from the higher level:
    - scheduler* to govern memory spaces
    - dispatcher* to govern processors
    - supervisor* to govern peripheral units etc.

## *Vertical description*

- VM<sub>5</sub> Presentation Layer ( in HOST)
  - R<sub>5</sub> resources = *logic* spaces of memory (files, databases etc.),  
*logic* processors which interpret instructions in language L<sub>4</sub>
  - L<sub>5</sub> language = symbolic programming language,  
standard language (C, C<sup>++</sup>, Java etc.  
+ HTML *for web documents description*)  
developed  
by having assembler instructions at a internal *sub-level*  
to VM<sub>5</sub> itself.

## *Vertical description*

- $VM_6$  Application Layer (in HOST)
  - $R_6$  = still *logic processors* and *logic* spaces of memory, but at a more abstract level of level 4 logics, in that the processors now interpret commands written in language L5
  - $L_6$  language = higher level language, or a synthetic language (menu commands etc.)
  - logic memory spaces gather all that has been created by user programs at this level, thus file icons, folders etc.

# Internet service (WPA program from HA (VM<sub>5</sub> / VM<sub>6</sub> level) towards HB)

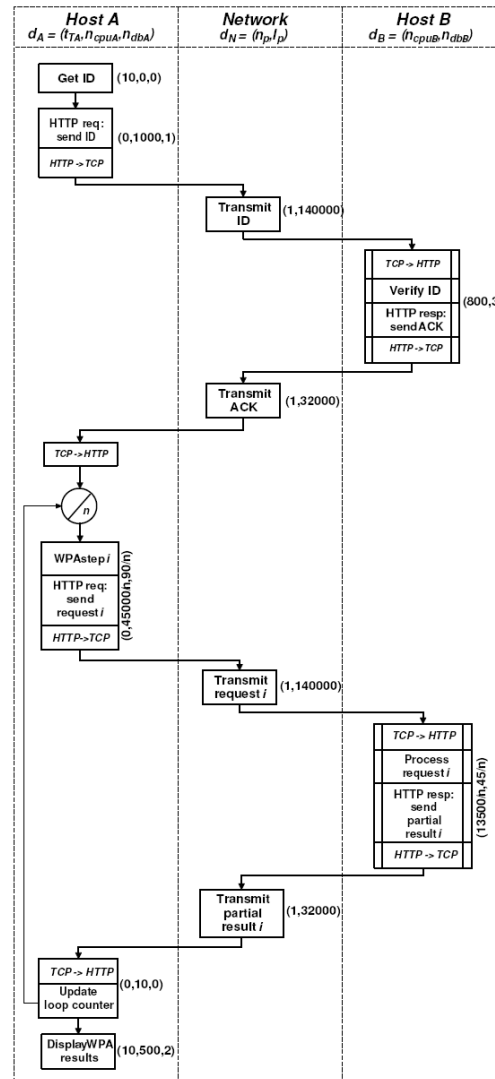

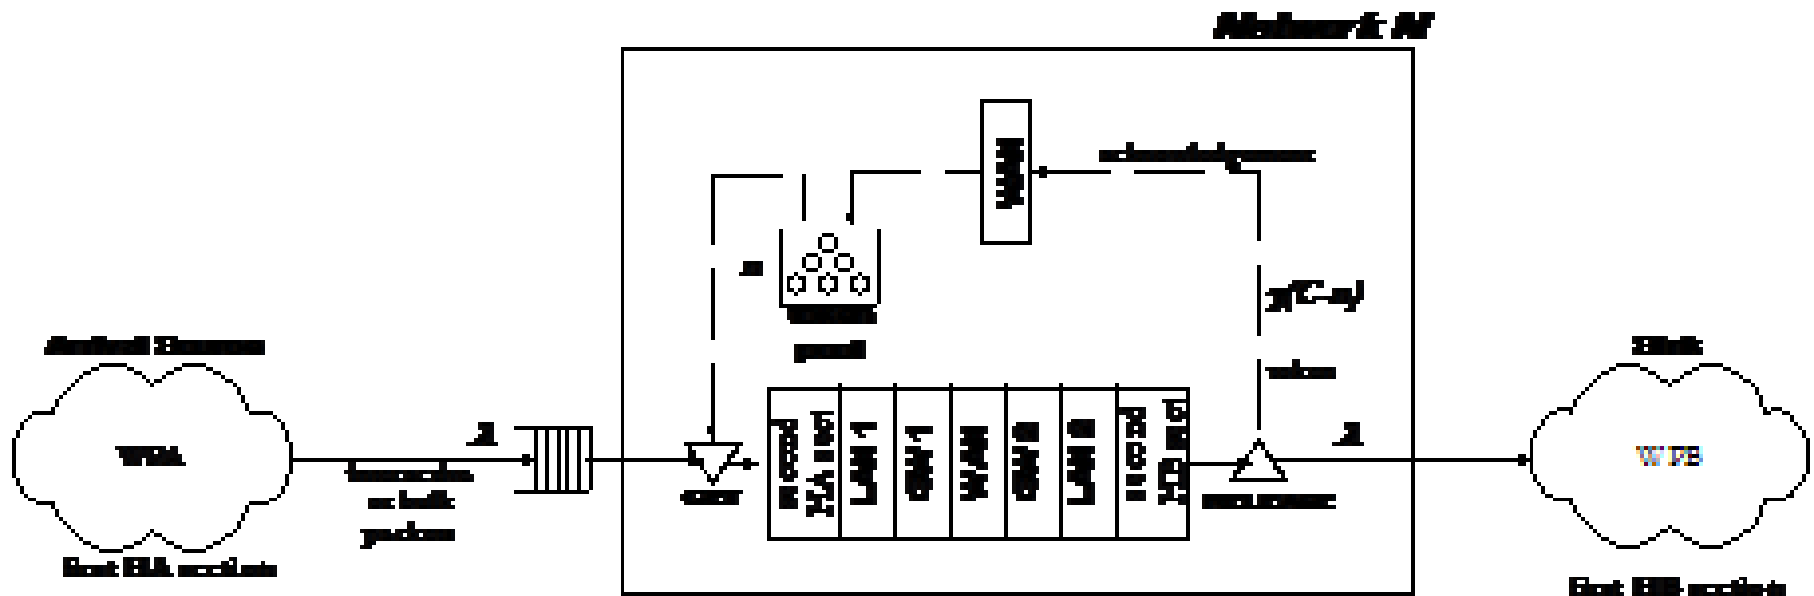

Fig. 3. Software model for the SpaceLab simulation

# WPA service towards platform

# Informal platform model, WPA&WPB services and protocols

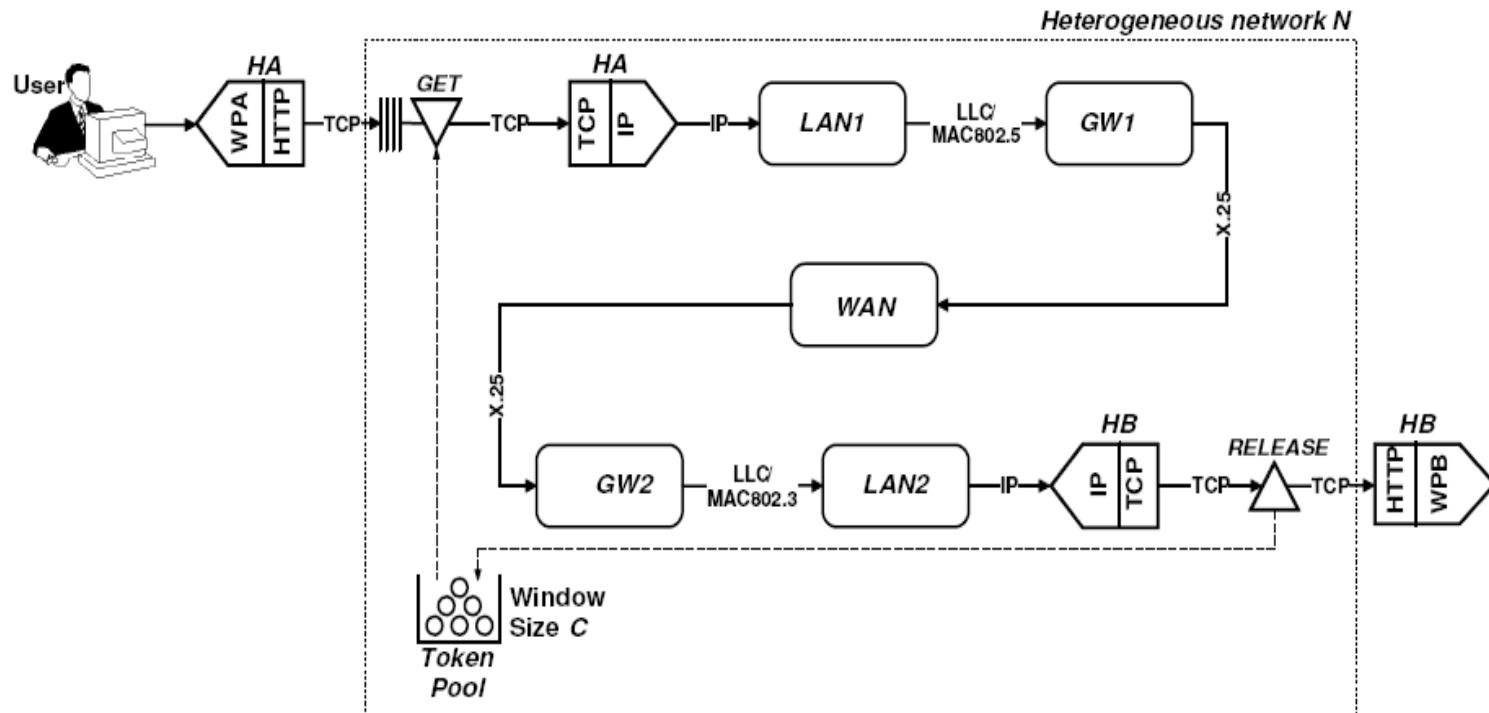

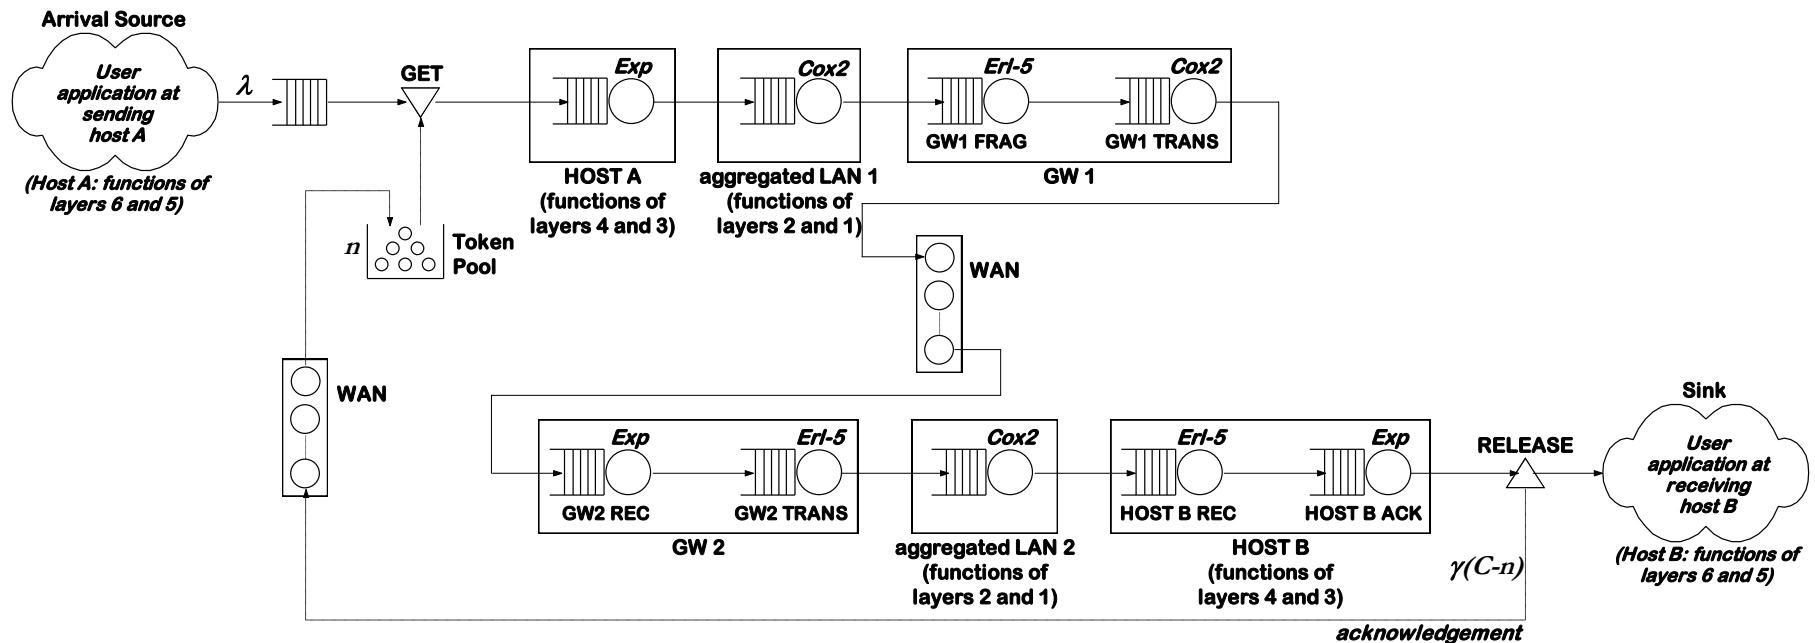

Fig. 2. Detailed view of the packet flow in the system platform when transferring data from HA to HB

# Formal platform model, WPA&WPB services and protocols

## Calculations on formal models: response time

- A is an access node (host)
- *response time* seen by A =  
= time from the instant in which a user in A launches a request to another resource R of the distributed imp., to the instant in which the response from R arrives to the user

= from A to R journey time

+ from R to A return time

## end-to-end delay

- *If  $R = \text{other host } B$*

where another user is the one which wants to communicate with A (or vice versa).

only interests the message journey time from A to B (or vice versa)

- This time is called **end-to-end delay** =  
= delay from one end to another of the platform

## Calculations on the formal model: *network throughput*

- A is an access node (host)
- B is a node (host) which interacts with A

**throughput** of the network =

= Number of packets per unit of time that transit via the network

Example of results from the formal model  
*prediction of the window size effect on the end-to-end delay*

Example of results from the formal model  
*prediction of the window size effect on the system capacity*

Example of results from the formal model  
(predict the execution time  $E(t)$  of the internet service)  
*study of the processing power effect of HA and HB and the workload  
platform  $n$*

- The average execution time  $E(t)$  is **the sum** of the response times the application **spends in the various** service centers visited by application tasks.
- In other words  $E(t)$  is the global, or end-to-end response time (*in both directions*).
- We assume that the designer is interested in **predicting the effect on  $E(t)$**  of concentrating the processing power in HA or HB for a given capacity of the network  $N$ .
- Predict  $E(t)$   
versus 7 different combinations of  
the processing power  $C_a$  and  $C_b$  of HA and HB,

(predict the internet service execution time)  
*study of the processing power effect of HA and HB and the workload  
platform **n***

- Various values of the reference processing power  $C$  were experimented up to finding out the two most significant cases:
  - a) *the network is not the system bottleneck*
  - b) *the network is the system bottleneck*
- For a network  $N$  with standard logical capacity values of various centers from HA to LAN1 to WAN to etc...to HB, it was found that
$$C = 10^3 \text{ statements/sec}$$
and
$$C = 10^5 \text{ statements/sec}$$
- were the values of the reference processing power  $C$  to obtain the cases a) and b) respectively.

(predict the internet service execution time)  
*study of the processing power effect of HA and HB and the workload  
platform  $n$*

- Seven different combinations of HA and HB processing power:

– (1)	$C_a = 5C$	$C_b = C$
– (2)	$C_a = 3C$	$C_b = C$
– (3)	$C_a = 2C$	$C_b = C$
– (4)	$C_a = C_b = C$	
– (5)	$C_a = C$	$C_b = 2C$
– (6)	$C_a = C$	$C_b = 3C$
– (7)	$C_a = C$	$C_b = 5C$

**Note:**

**When  $C = 10^3$  statements/sec** (network IS NOT the system bottleneck)

**When  $C = 10^5$  statements/sec** (network IS the system bottleneck)

(predict the internet service execution time)  
*study of the processing power effect of HA and HB and the workload  
platform  $n$*

- The value of the looping factor  $n$  gives the **network workload (platform workload)**
- Indeed, the demand vectors of all nodes included in the loop are divided by  $n$ , so that whichever is the value of  $n$ , the workload on HA and HB remains unchanged.
- On the contrary, the only workload that changes is the network workload, which is taken  $n$  times.
- The value  $n = 9$  was chosen as the lowest value in order to obtain a significant network workload.

(predict the internet service execution time)  
*study of the processing power effect of HA and HB and the workload  
platform  $n$*

Fig. 9.  $E(t)$  versus combinations of  $C_a$  and  $C_b$  for  $C = 10^3$  statements/sec (network is not the system bottleneck)

(predict the internet service execution time)  
*study of the processing power effect of HA and HB and the workload  
platform  $n$*

- When the network is NOT the system bottleneck, the host processing power has visible effects on  $E(t)$ :
- *$E(t)$  progressively decreases from its highest value  $E(t) = 131$  sec to significant lower values when the processing power is concentrated on either HA (left side of the curve) or HB (right side of the curve).*
- *In the former case a decrease from  $E(t) = 131$  to  $E(t) = 93$  sec is seen with a 29% decrease.*
- *In the latter one, a decrease to  $E(t) = 116$  is recognized, with a 11.5% decrease*

(predict the internet service execution time)  
*study of the processing power effect of HA and HB and the workload  
platform  $n$*

Fig. 10.  $E(t)$  versus combinations of  $C_a$  and  $C_b$  for  $C = 10^5$  statements/sec (network is the system bottleneck)

(predict the internet service execution time)  
*study of the processing power effect of HA and HB and the workload  
platform  $n$*

- Instead, when the network IS the system bottleneck:

there is no impact on  $E(t)$  of the processing power concentration on either HA or HB

Since the network is largely responsible for the delays

# Conclusions

- The dependence of the quality of the *internet service* on the
  - ***processing rates of the network versus*** the hosts
  - **and of the hosts**
- shows that **internet services** such as:
  - *distributed information retrieval*
  - *distributed interactive video*
  - *mobile telecommunication services*
  - *industrial process control*
  - *remote network management*
  - *network-based cooperative work*
  - *electronic commerce B2C , B2B, C2C*
  - *etc*
- can benefit from **formal model** studies from the **early phases of the internet development lifecycle** instead of using **fix it later** or **fly fix fly** approaches

# QoS platform control

Model-driven management of QoS  
of platforms and internet services

# QoS framework

- ISO/IEC 13236-1998 International Standard
- Structured collection of concepts to describe the Quality of Service (QoS) of IT systems
- Intended to assist those that produce specification and design of IT systems and those that define the communication services

- **QoS characteristic** of the network  
a quantified aspect of QoS, for example time delay, capacity, accuracy etc
- **QoS requirement**  
the user expectation of the QoS, for example, is the expectation that the time for a specific service (e.g. downloading a stream of data) must not exceed a specified value

# Considered QoS characteristics

- *capacity-related characteristic*

network *throughput*, i.e. number of packets per time unit delivered from source to sink through the network

- *time-related characteristic*

network *end-to-end delay*, i.e. the time for a packet to get across network

# Example of QoS requirements

- *capacity-related* characteristic
  - **E1**: the time to download a stream of data of  $x$  kByte of length from sending host A to receiving host B should not exceed  $y$  sec.
- *time-related* characteristic
  - **E2**: the time it takes host B to receive a command of one packet length sent from host A should not exceed  $z$  sec.

# QoS management/maintenance

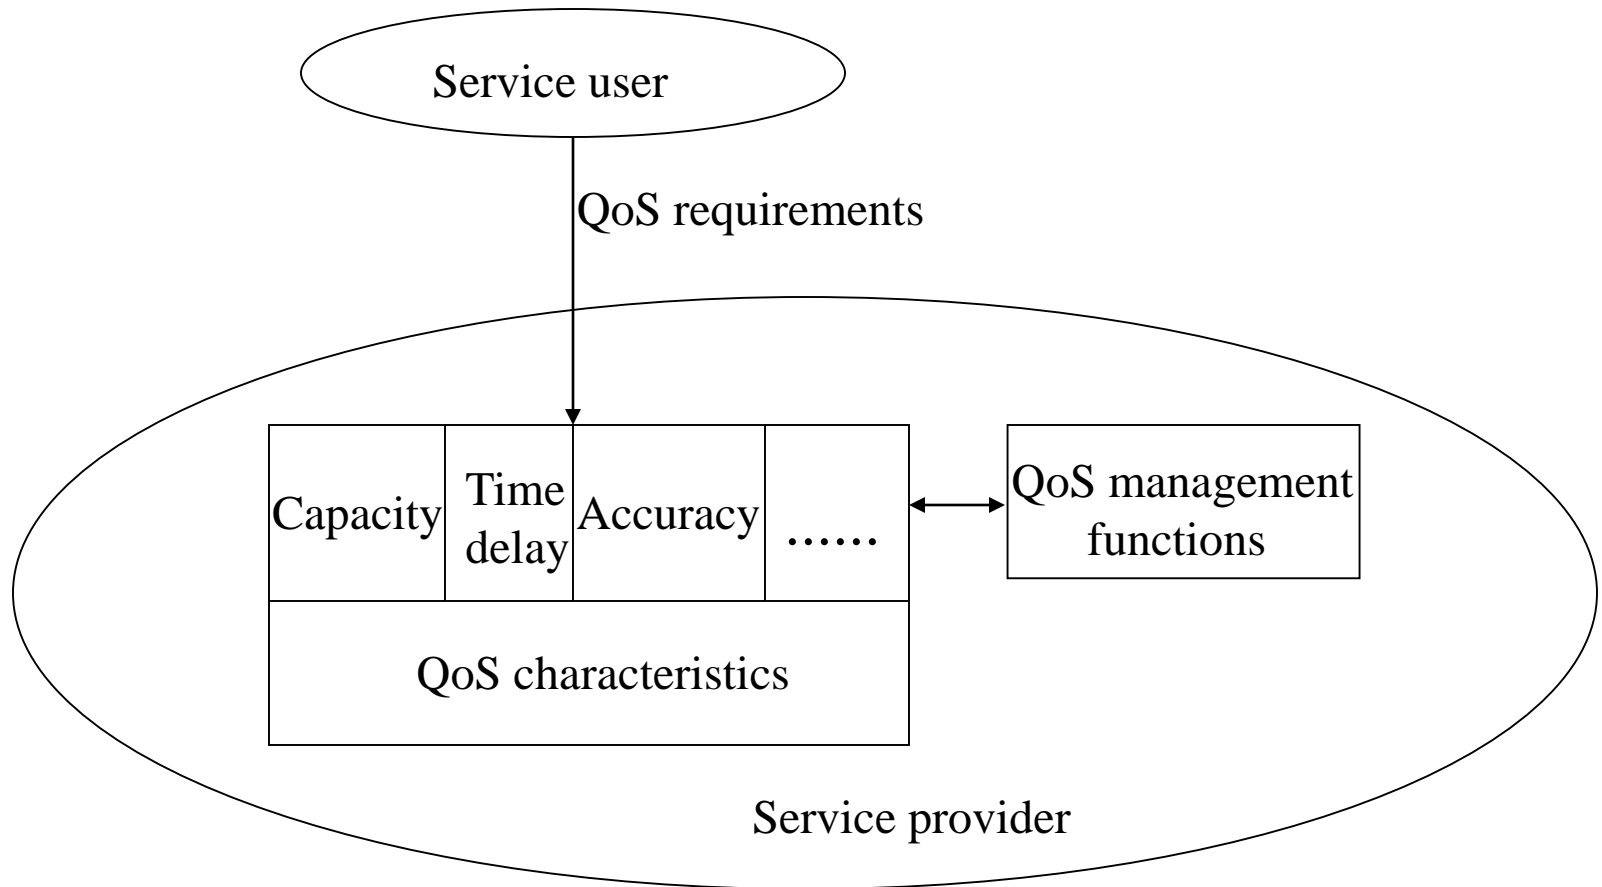

- network QoS **management**  
all activities designed to assist in satisfying one or more QoS requirements
- **operational phase** of QoS management  
management activities intended to honor the agreements on the QoS to be delivered
- network QoS **maintenance**  
the activity intended to maintain QoS to acceptable levels (**tuning** activity)

# QoS management/maintenance

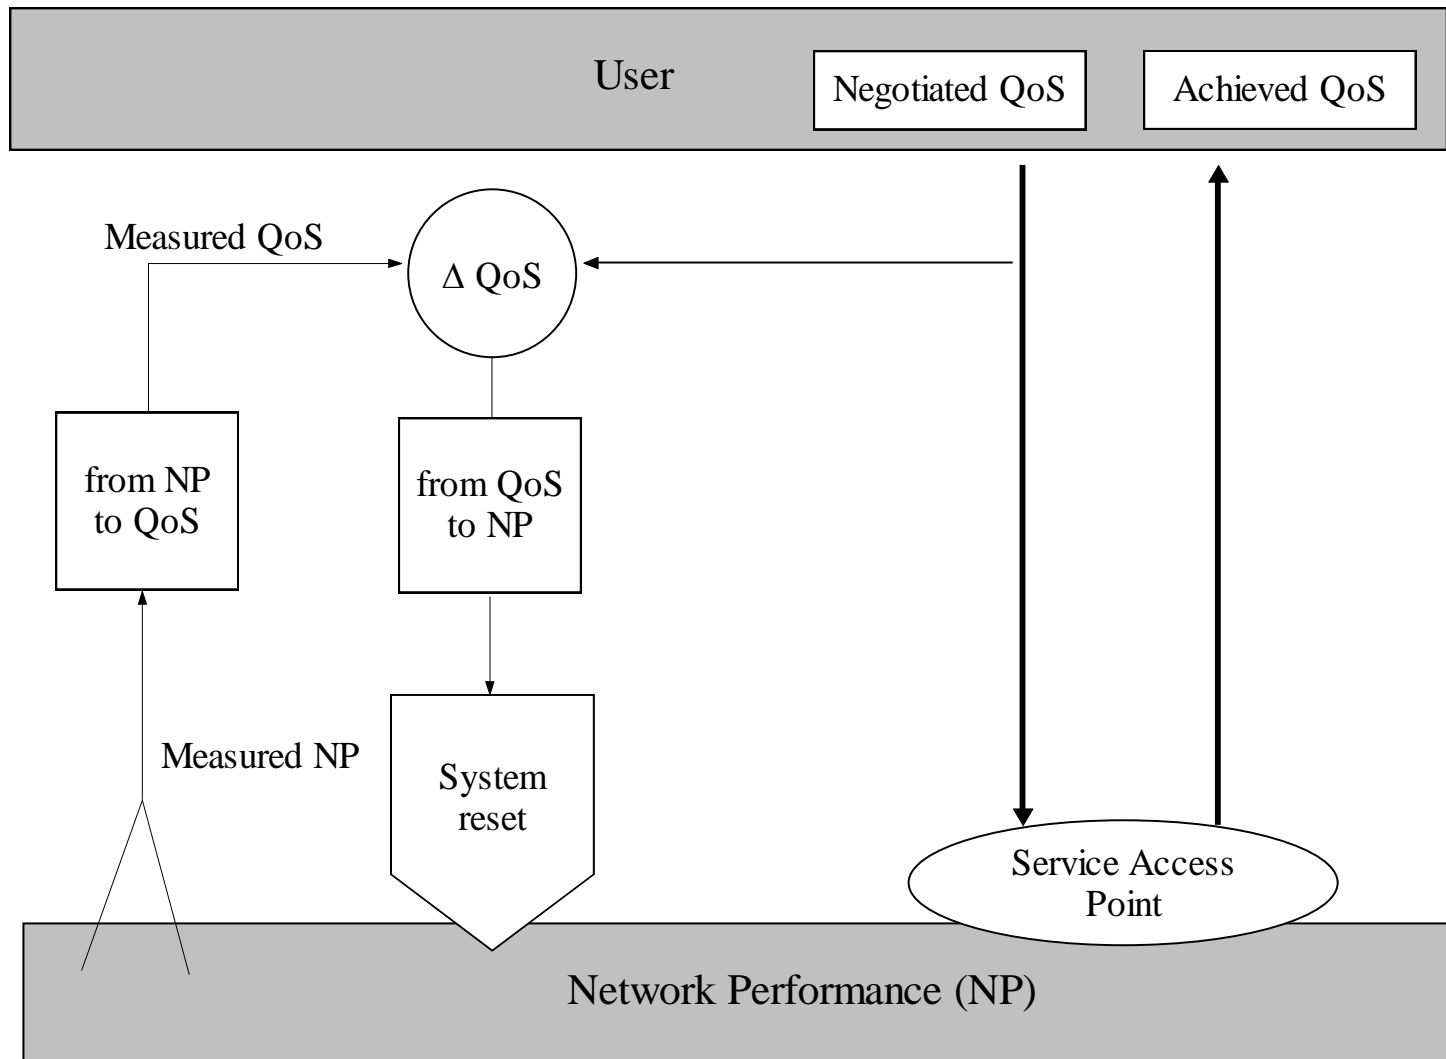

- Network **tuning**
  - a compensatory adjustment of the network operation
  - directed by an **efficient** performance model, an on-line approach to system evaluation

# Relationships between QoS concepts

# Network QoS tuning

## Time-efficiency of the performance model

- *model-based tuning* = identify the network variables to reset in a short time

time-efficiency essential  
to conduct the *decision process* in due time

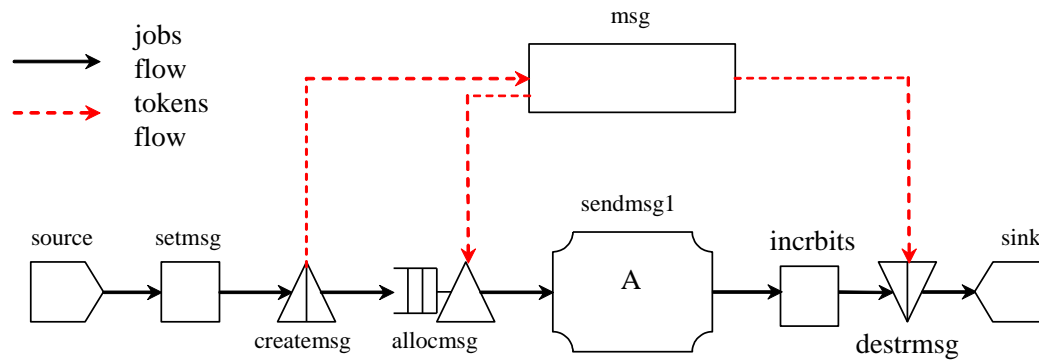

## Time-efficiency objective

Reduce model evaluation time from  
about 30 hours of the brute-force  
approach to a few seconds of the  
efficient approach

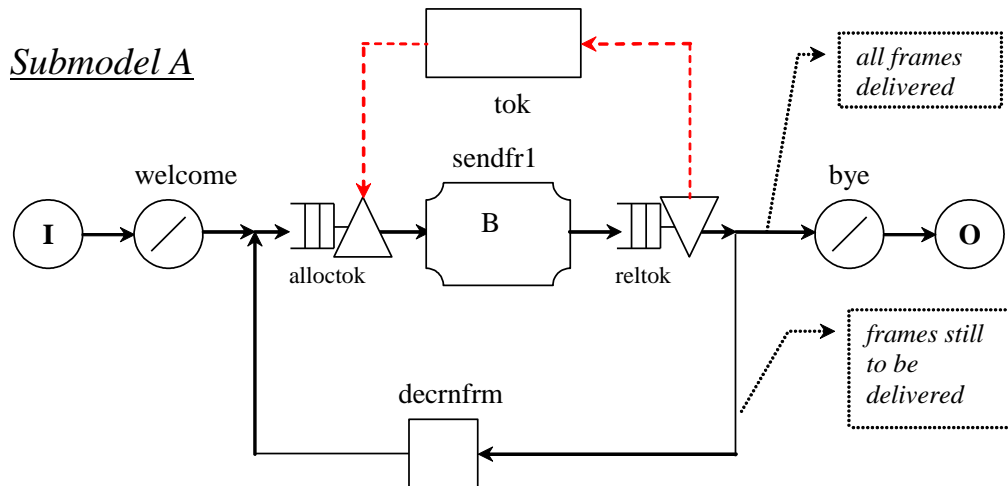

## Efficient evaluation method

- Hierarchical hybrid approach based on decomposition and aggregation
- Based on three abstraction levels

# Level-1 Model (part of)

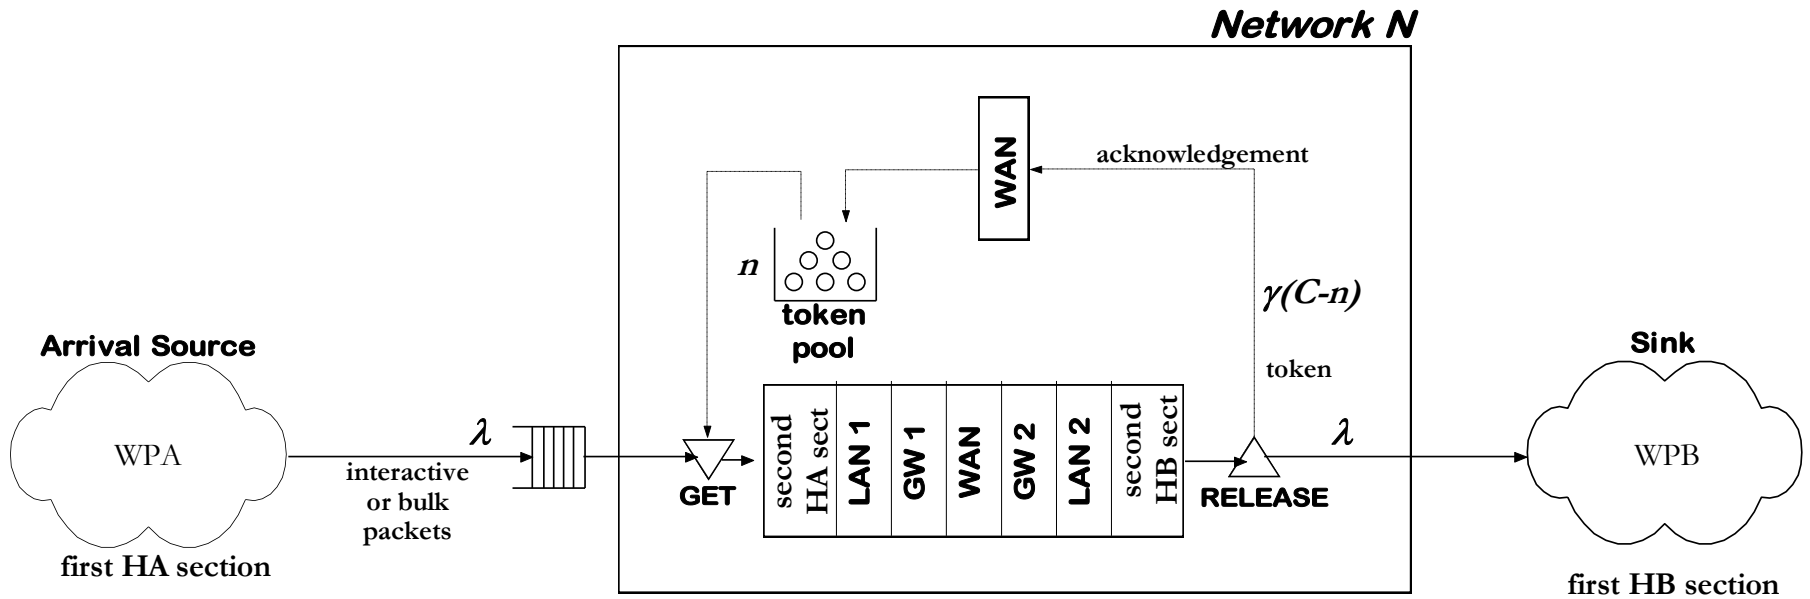

## Submodel A

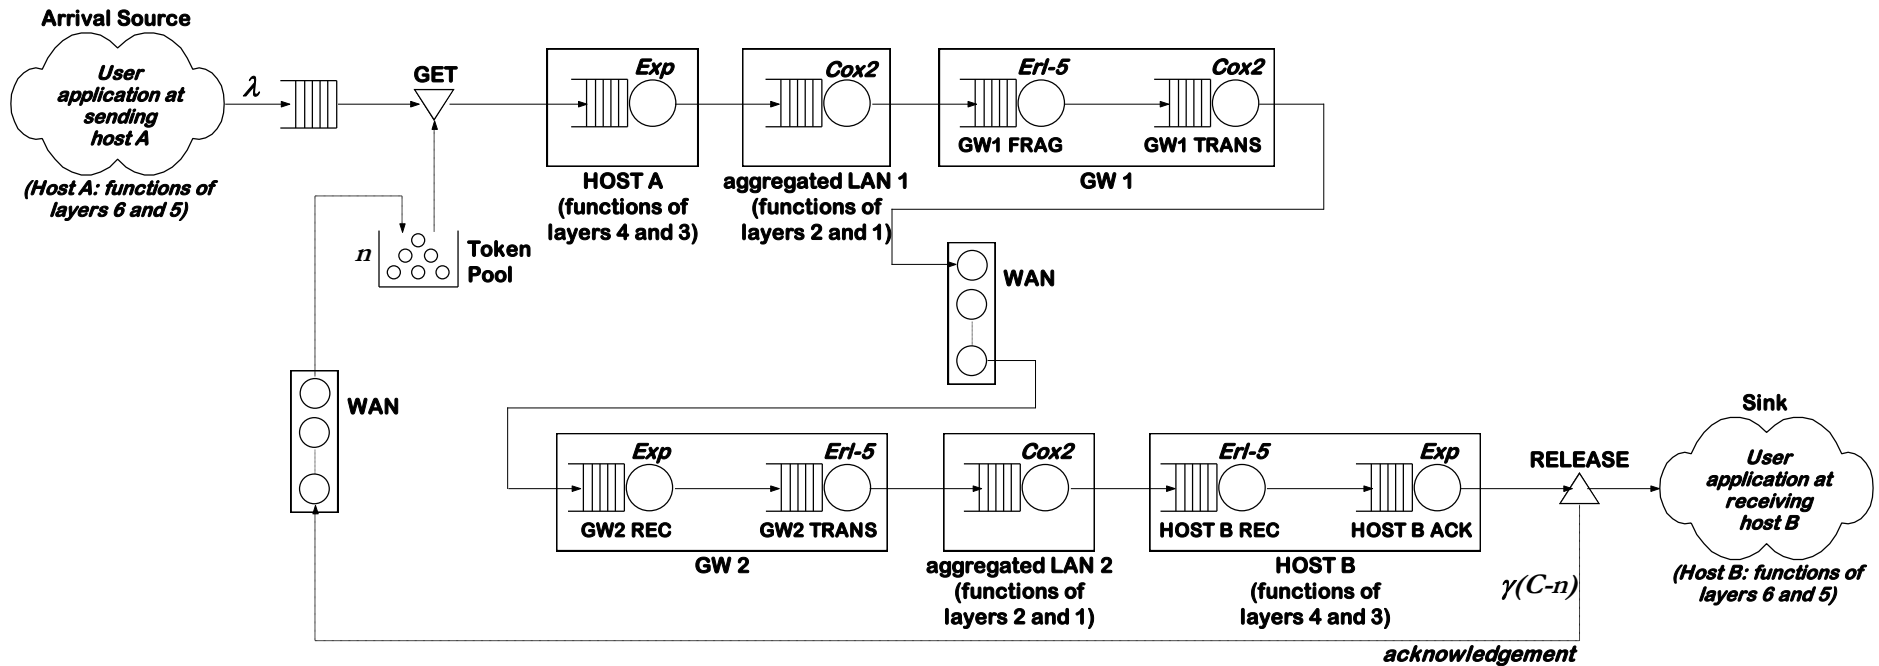

## Submodel B

# Level-2 Model

# Level-2 Model (expanded view)

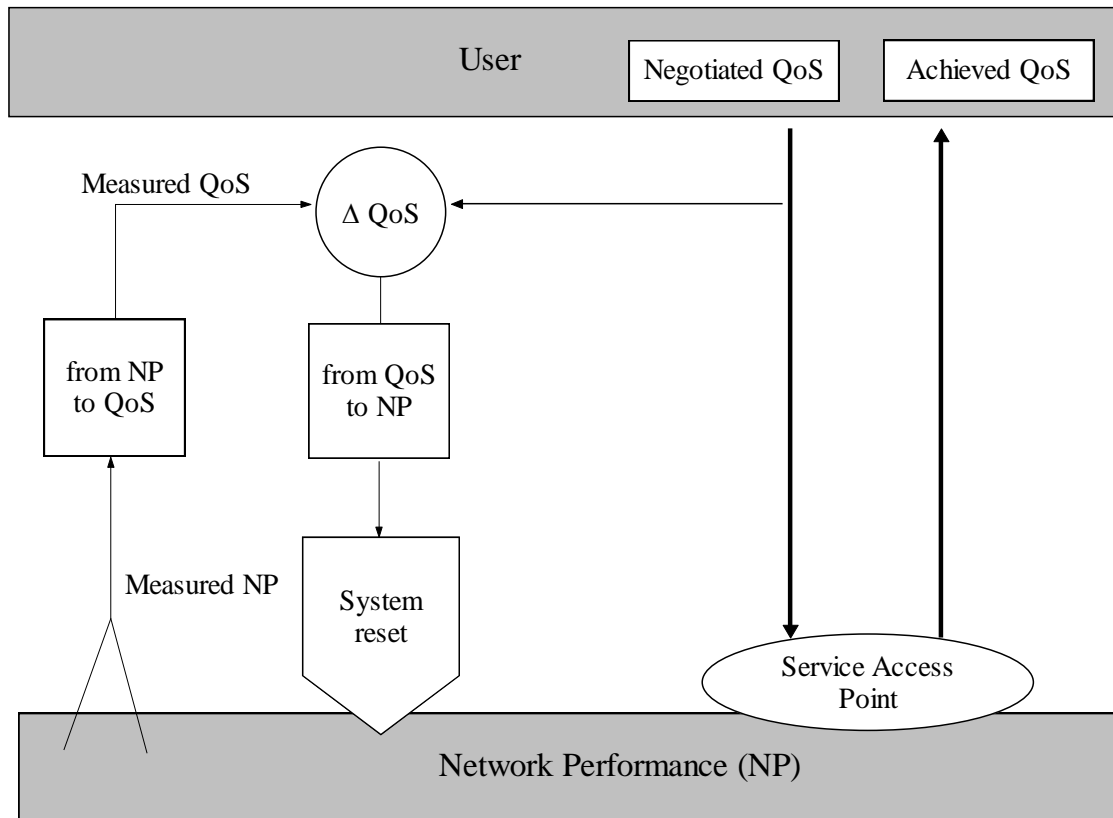

## Level-3 Model

$E(t_s)$  = function of ack throughput (  $\gamma(C-n)$  )

$$\begin{aligned} E(t_s) &= 1 / \gamma(i) \quad \text{for } 0 \leq i \leq C \\ &= 1 / \gamma(C) \quad \text{for } i > C \end{aligned}$$

# Network QoS tuning

- measurement** of the system performance (SP) characteristics, e.g. mean end-to-end delay or mean network capacity
- translation** to QoS values
- calculation of QoS **difference**
- identification of QoS related **components**
- modification** of parameters of identified components and system reset

# Decision process of tuning operations

The tuning decision process, i.e.:

- d) identification of QoS related  
**components**
- e) **modification** of parameters of  
identified components and  
system reset

... is performance-model driven

# Identification of QoS related components (step 1)

- QoS user requirement:
  - the time for downloading a stream of data must not exceed a specified value
- related QoS characteristics:
  - *end-to-end delay*
  - *network capacity*

# Identification of QoS related components (step 2)

- packet arrival process
- packet acknowledgement process

# Parameters of identified components

- arrival rate  $\lambda$  of user application packets
- network window size  $C$

# Network **reset** operations

Illustration of the effect of  
variables reset on the mean end-  
to-end delay and on the network  
capacity

# Effect on *end-to-end* delay

Mean end-to-end delay versus  $\lambda$

## Effect on *end-to-end* delay (2)

- Assume we are in the case of the QoS requirement E2, and that the negotiated QoS is a time of no more than 15 seconds to deliver a command of one packet length to B.
- By using the model, it is possible to find the values of the parameters  $\lambda$  or  $C$  that guarantee a mean end-to-end delay lower than or equal to 15 seconds. By looking at the previous figure it is easily seen that:
  - for  $\lambda \leq 2,8$  all values of the window size  $C$  (4, 7 or 12) can be chosen,
  - for  $2,8 < \lambda \leq 3,8$   $C=7$  or  $C=12$  can be chosen,
  - for  $3,8 < \lambda \leq 4,3$  only  $C=12$  can be chosen,while no values of  $C$  can guarantee the considered requirement if  $\lambda > 4,3$ .

# Effect on *network capacity*

Network capacity versus  $\lambda$

## Effect on *network capacity* (2)

- Assume we are in the case of the QoS requirement E1, and that the negotiated QoS is a time of no more than 10 seconds to download a stream of data of 140 Kbytes. In other words, a throughput of no less than 14 Kbytes/sec, or 1,75 packets/sec for packets of 8 Kbytes length, is required.
- By using the model, it is possible to find the values of the parameters  $\lambda$  or  $C$  that guarantee a mean network throughput greater than or equal to 1,75 packets per second. By looking at previous figure we can easily see that for  $1,75 \leq \lambda \leq 2$  only a window size  $C=12$  can be chosen, while for  $\lambda > 2$   $C=7$  can be chosen as well.

# Conclusions

- Performance modeling is called to play an important role in the network QoS management activities
- To play such a role, however, some important improvements need to be achieved in the modeling research and application
  - Methods for QoS-oriented model production
  - Model capability in identifying QoS-related components and parameters
  - Model evaluation effectiveness for its on-line use in the tuning operation loop

*Complete development of the formal model*
